t-test: `t.test()`

One-sample t-test

▶ compares the mean of a sample with a fixed value μ

Two sample / independent samples t-test

▶ compares the difference between the means of two samples with a fixed value μ

Related samples t-test

▶ compares the mean of the difference between related observations with a fixed value μ (same as one-sample t-test)

Wilcoxon Test: `wilcox.test()`

Wilcoxon Signed Rank Test

► tests if one sample (or the differences between two paired samples) is/are symmetric about μ

Wilcoxon Rank Sum Test / Mann-Whitney test

► test for a location shift between the distributions of two independent samples

See also BBR Sections 7.2 & 7.3 (http://hbiostat.org/doc/bbr.pdf)

Kruskal-Wallis Rank Sum Test: `kruskal.test()`

- ► This is an extension of the Wilcoxon rank sum test for more than two groups
- ► Test for a difference in location of a continuous variable between multiple groups
- ► The Wilcoxon rank sum test is a special case of the Kruskal-Wallis rank sum test

Other tests for continuous data

- **Kolmogoriv-Smirnov Test:** `ks.test()`
  tests if two samples are drawn from the same continuous distribution
- **Shapiro-Wilk Normality Test:** `shapiro.test()`
- **Friedman Rank Sum Test:** `friedman.test()`
  non-parametric test for 2 or more related samples
- …

Tests for Categorical Data / Proportions

One-sample Proportion Test

- ▶ tests if the proportion in one sample is equal to a fixed value *p*
- ▶ `prop.test()` and `binom.test()`

Tests for Proportions in Multiple (independent) Groups

- ▶ tests if the proportion in several samples are equal
- ▶ `chisq.test()` and `fisher.test()` (when there are cells with 0)

See also BBR Sections 5.7 & 6 (http://hbiostat.org/doc/bbr.pdf)

Tests for Categorical Data / Proportions

Related Samples: McNemar Test

- ► Tests for symmetry in a 2×2 table
- ► `mcnemar.test()`

3-Dimensional Contingency Table

- ► Cochrane-Mantel-Haenszel Test
- ► χ^2 test for independence of two nominal variables in each stratum
- ► `mantelhaen.test()`

Statistical Tests

Continuous Outcomes

- ► `t.test()`
- ► `wilcox.test()`
- ► `kruskal.test()`
- ► `ks.test()`
- ► `friedman.test()`
- ► `shapiro.test()`

Categorical Outcomes

- ► `prop.test()`
- ► `binom.test()`
- ► `chisq.test()`
- ► `fisher.test()`
- ► `mcnemar.test()`
- ► `mantelhaen.test()`

Pairwise tests

- ► `pairwise.prop.test()`
- ► `pairwise.t.test()`
- ► `pairwise.wilcox.test()`

Variance and Correlation

- ► `cor.test()`
- ► `bartlett.test()`
- ► `var.test()`

Linear Regression

A standard linear regression model has the form

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_p x_p + \varepsilon \qquad \text{with } \varepsilon \sim N(0, \sigma^2)$$

where

- ► y is the **outcome** variable ("dependent variable")
- ► $x_1, \ldots, x_p$ are the **covariates** ("independent variables")
- ► $\beta_0, \ldots, \beta_p$ are the **regression coefficients**
    - ► β_0 is the intercept
    - ► $\beta_1, \ldots, \beta_p$ estimate the effects of the covariates
- ► ε is a vector of **residuals**, which we assume to be (approximately) normally distributed.

Linear Regression

To fit a **linear regression** in R we use the function `lm()`.

The most important arguments are

- ► `formula`:
  a formula object
- ► `data`:
  a data.frame (optional, but usually needed)
- ► `subset`:
  a vector specifying which observations should be used (optional)

Model Formula

A `formula` object has the form

```
outcome ~ linear predictor
```

for example

```
y ~ x1 + x2 + x3
```

- ► Variables are separated by "**+**" signs.
- ► An intercept is automatically included.
- ► one-sided formulas (omitting the outcome) are possible
  (used for random effects specification)

Model Formula: Interactions

Interaction terms are written using ":" or "*".

"*" includes the main effects and interaction terms, i.e.,

```
y ~ x1 * x2
```

is equivalent to

```
y ~ x1 + x2 + x1:x2
```

Interactions between multiple variables can be written using "()", i.e.,

```
y ~ x1 * (x2 + x3)
```

is equivalent to

```
y ~ x1 * x2 + x1 * x3
```

Model Formula: Interactions

To specify a **higher level interaction** (for example a three-way interaction) "`^`" is used, i.e.,

```
y ~ (x1 + x2 + x3)^3
```

will create all interactions up to 3-way and is equivalent to

```
y ~ x1 * x2 * x3
```

and equivalent to

```
y ~ x1 + x2 + x3 + x1:x2 + x1:x3 + x2:x3 + x1:x2:x3
```

and

```
y ~ (x1 + x2 + x3)^2
```

will create all two-way interactions and is equivalent to

```
y ~ x1 + x2 + x3 + x1:x2 + x1:x3 + x2:x3
```

Model Formula: Removing terms

The "**−**" sign can be used to remove terms from a model formula, for example

```
y ~ x1 * x2 * x3 − x2 − x1:x3
```

is equivalent to

```
y ~ x1 + x3 + x1:x2 + x2:x3 + x1:x2:x3
```

The **intercept** can be removed from a formula by using "**−1**" or "**+0**", i.e.

```
y ~ x1 + x2 − 1
y ~ x1 + x2 + 0
```

Generalized Linear Regression (GLM)

A **generalized linear regression** model has the form

$$g(\mathbb{E}(y)) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_p x_p$$

where $g(\ )$ is a link function and y is from the exponential family.

For example **logistic regression** for binary y:

$$log\left(\frac{P(y = 1)}{1 - P(y = 1)}\right) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_p x_p$$

$log\left(\frac{p}{1-p}\right)$ is the **logit** link.

Generalized Linear Regression (GLM)

To fit a **GLM** in R we use the function `glm()`.

The most important arguments are

- ► `formula`:
  a `formula` object
- ► `family`:
  a `family` object or name of the family function, describing the error distribution and link function
- ► `data`:
  a `data.frame` (optional, but usually needed)
- ► `subset`:
  a `vector` specifying which observations should be used (optional)

Families and Link Functions

Common families & available links in R: (see also `?family`)

family	link
binomial	logit, probit, cauchit, log, cloglog
gaussian	identity, log, inverse
Gamma	inverse, identity, log
poisson	log, identity, sqrt

The `family` argument in `glm()` can be specified in the following ways:

▶ `binomial(link = "logit")`
▶ `binomial()`
▶ `binomial`
▶ `"binomial"`

Note:
When the link is not explicitely specified (i.e. option 1), the default link is used.
